

Vector Functions

Definition: The Limit of a Vector Function

Let $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k}$ be a vector function with domain D , and let \mathbf{L} be a vector. We say that \mathbf{r} has **limit** \mathbf{L} as t approaches t_0 and write

$$\lim_{t \rightarrow t_0} \mathbf{r}(t) = \mathbf{L}$$

if, for every $\epsilon > 0$, there exists a corresponding $\delta > 0$ such that for all $t \in D$

$$\|\mathbf{r}(t) - \mathbf{L}\| < \epsilon \text{ whenever } 0 < |t - t_0| < \delta$$

(Just take the lim of each of the funtions)

Limit Rules

Let \mathbf{f} and \mathbf{g} be vector functions and let u be a real-valued function. If we are given that as $t \rightarrow t_0$

$$\mathbf{f}(t) \rightarrow \mathbf{L}, \quad \mathbf{g}(t) \rightarrow \mathbf{M}, \quad u(t) \rightarrow U$$

Then,

$$(1) \mathbf{f}(t) + \mathbf{g}(t) \rightarrow \mathbf{L} + \mathbf{M},$$

$$(2) \alpha \mathbf{f}(t) \rightarrow \alpha \mathbf{L},$$

$$(3) u(t)\mathbf{f}(t) \rightarrow U\mathbf{L},$$

$$(4) \mathbf{f}(t) \cdot \mathbf{g}(t) \rightarrow \mathbf{L} \cdot \mathbf{M},$$

$$(5) \mathbf{f}(t) \times \mathbf{g}(t) \rightarrow \mathbf{L} \times \mathbf{M}.$$

Derivative

Definition: Derivative of a Vector Function

The **derivative** of a vector function is found by:

$$\mathbf{r}'(t) = \lim_{\Delta t \rightarrow 0} \frac{\mathbf{r}(t + \Delta t) - \mathbf{r}(t)}{\Delta t}$$

providing this limit exists. When the limit exists, we say that \mathbf{r} is *differentiable* at t and $\mathbf{r}'(t)$ is called the *derivative* of \mathbf{r} at t .

$$(1) (\mathbf{f} + \mathbf{g})'(t) = \mathbf{f}'(t) + \mathbf{g}'(t)$$

$$(2) (\alpha \mathbf{f})'(t) = \alpha \mathbf{f}'(t)$$

$$(3) (\mathbf{f} \cdot \mathbf{g})'(t) = [\mathbf{f}(t) \cdot \mathbf{g}'(t)] + [\mathbf{f}'(t) \cdot \mathbf{g}(t)]$$

$$(4) (\mathbf{f} \times \mathbf{g})'(t) = [\mathbf{f}(t) \times \mathbf{g}'(t)] + [\mathbf{f}'(t) \times \mathbf{g}(t)]$$

$$(5) (u\mathbf{f})'(t) = u(t)\mathbf{f}'(t) + u'(t)\mathbf{f}(t)$$

$$(6) (\mathbf{f} \circ u)'(t) = \mathbf{f}'(u(t)) u'(t)$$

The curve is smooth if the derivative of the curve is continuous and never 0.

The direction of motion is the direction of the velocity vector.

Integrals

Definition: Indefinite Integral

A differentiable vector function $\mathbf{R}(t)$ is an **antiderivative** of $\mathbf{r}(t)$ on some interval I if $\frac{d\mathbf{R}}{dt} = \mathbf{r}$ at each point of I . The **indefinite integral** of \mathbf{r} with respect to t is the set of all antiderivatives of \mathbf{r} , denoted by $\int \mathbf{r} dt$. If \mathbf{R} is any antiderivative of \mathbf{r} , then

$$\int \mathbf{r} dt = \mathbf{R}(t) + \mathbf{C}$$

Definition: The Definite Integral

For $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k}$ continuous on $[a, b]$,

$$\int_a^b \mathbf{r}(t) dt = \left(\int_a^b f(t) dt \right) \mathbf{i} + \left(\int_a^b g(t) dt \right) \mathbf{j} + \left(\int_a^b h(t) dt \right) \mathbf{k}$$

Properties of the Integral

- (1) $\int_a^b [\mathbf{f}(t) + \mathbf{g}(t)] dt = \int_a^b \mathbf{f}(t) dt + \int_a^b \mathbf{g}(t) dt$
- (2) $\int_a^b [\alpha \mathbf{f}(t)] dt = \alpha \int_a^b \mathbf{f}(t) dt$ (α a constant scalar)
- (3) $\int_a^b [\mathbf{c} \cdot \mathbf{f}(t)] dt = \mathbf{c} \cdot \int_a^b \mathbf{f}(t) dt$ (\mathbf{c} a constant vector)
- (4) $\left\| \int_a^b \mathbf{f}(t) dt \right\| \leq \int_a^b \|\mathbf{f}(t)\| dt$
